

# A UNIVERSAL PROPERTY FOR THE JIANG-SU ALGEBRA

MARIUS DADARLAT AND ANDREW S. TOMS

ABSTRACT. We prove that the infinite tensor power of a unital separable  $C^*$ -algebra absorbs the Jiang-Su algebra  $\mathcal{Z}$  tensorially if and only if it contains, unitaly, a subhomogeneous algebra without characters. This yields a succinct universal property for  $\mathcal{Z}$  in a category so large that there are no unital separable  $C^*$ -algebras without characters known to lie outside it. This category moreover contains the vast majority of our stock-in-trade separable amenable  $C^*$ -algebras, and is closed under passage to separable superalgebras and quotients, and hence to unital tensor products, unital direct limits, and crossed products by countable discrete groups.

One consequence of our main result is that strongly self-absorbing ASH algebras are  $\mathcal{Z}$ -stable, and therefore satisfy the hypotheses of a recent classification theorem of W. Winter. One concludes that  $\mathcal{Z}$  is the only projectionless strongly self-absorbing ASH algebra, completing the classification of strongly self-absorbing ASH algebras.

## 1. INTRODUCTION

The Jiang-Su algebra  $\mathcal{Z}$  is one of the most important simple separable amenable  $C^*$ -algebras. It has become apparent in recent years that the property of absorbing the Jiang-Su algebra tensorially—being  $\mathcal{Z}$ -stable—is the essential property which allows one to analyse the fine structure of a simple separable amenable  $C^*$ -algebra using Banach algebra  $K$ -theory and traces. Instances of this phenomenon can be found in the classification theory of amenable  $C^*$ -algebras (see [13] for an introduction to this subject, and [6] for a recent survey), and more recently in parameterisations of unitary orbits of self-adjoint operators on Hilbert space relative to an ambient amenable  $C^*$ -algebra (see [2] and [1]). In spite of this,  $\mathcal{Z}$  has only had an *ad hoc* description since its discovery in 1997. The best result concerning the uniqueness of  $\mathcal{Z}$  has been that it is determined up to isomorphism by its  $K$ -theory and tracial simplex in a very restricted class of inductive limit  $C^*$ -algebras. The main result of this article concerns the  $\mathcal{Z}$ -stability of the infinite tensor power of a unital separable  $C^*$ -algebra. This result has several consequences for the theory of strongly-self absorbing  $C^*$ -algebras. In particular it shows that the Jiang-Su algebra satisfies an attractive universal property.

*Key words and phrases.* Jiang-Su algebra, strongly self-absorbing  $C^*$ -algebras.

M.D. was partially supported by NSF grant #DMS-0500693; A.T. was partially supported by NSERC.

Let  $\mathcal{C}$  be a class of unital  $C^*$ -algebras. For  $A \in \mathcal{C}$ , we let  $A^{\otimes\infty}$  denote the infinite minimal tensor product of countably many copies of  $A$ . (All  $C^*$ -algebra tensor products in the sequel are assumed to be minimal.) The following pair of conditions on a  $C^*$ -algebra  $B \in \mathcal{C}$  constitute a universal property, which we will denote by (UP) (cf. [16]):

- (i)  $B^{\otimes\infty} \cong B$ ;
- (ii)  $B \otimes A^{\otimes\infty} \cong A^{\otimes\infty}$ ,  $\forall A \in \mathcal{C}$ .

It is easy to see that if  $B_1, B_2 \in \mathcal{C}$  satisfy properties (i) and (ii), then they are isomorphic. To wit,

$$B_1 \stackrel{(i)}{\cong} B_1^{\otimes\infty} \stackrel{(ii)}{\cong} B_1^{\otimes\infty} \otimes B_2 \stackrel{(i)}{\cong} B_1 \otimes B_2^{\otimes\infty} \stackrel{(ii)}{\cong} B_2^{\otimes\infty} \stackrel{(i)}{\cong} B_2.$$

The question, of course, is whether a given class  $\mathcal{C}$  contains an algebra  $B$  satisfying (i) and (ii) at all. Recall that a  $C^*$ -algebra is *subhomogeneous* if all of its irreducible representations are finite-dimensional, and also that  $\mathcal{Z}^{\otimes\infty} \cong \mathcal{Z}$  ([7]). Our main result is the following theorem.

**Theorem 1.1.** *Let  $A$  be a unital separable  $C^*$ -algebra. Suppose that  $A^{\otimes\infty}$  contains, unitaly, a subhomogeneous algebra without characters. It follows that*

$$A^{\otimes\infty} \otimes \mathcal{Z} \cong A^{\otimes\infty}.$$

*In particular,  $\mathcal{Z}$  satisfies (UP) in the class  $\mathcal{C}$  consisting of all such  $A$ .*

The necessity of taking the infinite (as opposed to some finite) tensor power of  $A$  in Theorem 1.1 is evident from the fact that  $A$  itself may be subhomogeneous without characters: any finite tensor power of such an algebra is again subhomogeneous, but no  $C^*$ -algebra which absorbs  $\mathcal{Z}$  tensorially can have finite-dimensional representations. This necessity also persists in the case that  $A$  is simple and infinite-dimensional: [16] contains an example of a simple unital separable infinite-dimensional  $C^*$ -algebra  $A$  with the property that  $A^{\otimes n} \otimes \mathcal{Z} \not\cong A^{\otimes n}$  for each  $n \in \mathbb{N}$  and yet  $A^{\otimes\infty} \otimes \mathcal{Z} \cong A^{\otimes\infty}$ .

The bulk of the difficulty in establishing Theorem 1.1 is overcome by Theorem 5.3, which states that the space of unital  $*$ -homomorphisms

$$\mathrm{Hom}_1(I_{p,q}; M_k(C(X))) \equiv C(X; \mathrm{Hom}_1(I_{p,q}; M_k))$$

is path connected whenever  $k$  is large relative to  $\dim(X)$ ; in particular, the homotopy groups of  $F^k := \mathrm{Hom}_1(I_{p,q}; M_k)$  vanish in dimensions  $< ck$  where  $c \in (0, 1)$  depends only on  $p, q$ . We prove this result by filtering the non-manifold  $F^k$  so that the successive differences in the filtration are smooth manifolds, applying Thom's transversality theorem to perturb maps into the said differences, applying a continuous selection argument to semicontinuous fields of representations of  $I_{p,q}$ , and finally appealing to Kasparov's KK-theory. (Here  $I_{p,q}$  denotes the prime dimension drop algebra associated to the relatively prime integers  $p$  and  $q$ —see Section 2 for its definition—and  $M_k$  denotes the set of  $k \times k$  matrices with complex entries.)

The subalgebra hypothesis of Theorem 1.1 is not only necessary ( $\mathcal{Z}$  contains, unitaly, a subhomogeneous algebra without characters), but also extremely weak. Indeed, it is potentially vacuous for unital separable  $C^*$ -algebras without characters. Examples of unital separable  $C^*$ -algebras known to lie in  $\mathcal{C}$  include the following (we explain why in Section 6):

- (a) simple exact  $C^*$ -algebras containing an infinite projection;
- (b) inductive limits of subhomogeneous algebras (ASH algebras) without characters;
- (c) properly infinite  $C^*$ -algebras;
- (d) real rank zero  $C^*$ -algebras without characters;
- (e)  $C^*$ -algebras arising from minimal dynamics on a compact infinite Hausdorff space;
- (f) algebras considered pathological with respect to the strong form of Elliott's classification conjecture for separable amenable  $C^*$ -algebras ([14], [17], [18]).

The question of whether (a) and (b) together encompass the class of simple unital separable amenable  $C^*$ -algebras entire is an outstanding open problem. Note that the hypotheses of Theorem 1.1 imply immediately that  $\mathcal{C}$  is closed under passage to unital separable superalgebras and quotients. In particular,  $\mathcal{C}$  is closed under arbitrary unital tensor products, unital direct limits and crossed products by countable discrete groups.

The Jiang-Su algebra is an example of a strongly self-absorbing  $C^*$ -algebra, i.e., a unital separable  $C^*$ -algebra  $\mathcal{D} \not\cong \mathcal{C}$  such that the factor inclusion  $\mathcal{D} \otimes 1_{\mathcal{D}} \hookrightarrow \mathcal{D} \otimes \mathcal{D}$  is approximately unitarily equivalent to a  $*$ -isomorphism ([19]). Such algebras are automatically simple and amenable. They also rare, and connected deeply to the classification theory of separable amenable  $C^*$ -algebras. Among Kirchberg algebras—simple separable amenable purely infinite  $C^*$ -algebras satisfying the UCT—there are only  $\mathcal{O}_2$ ,  $\mathcal{O}_\infty$ , and tensor products of  $\mathcal{O}_\infty$  with UHF algebras of “infinite type” (tensor products of countably many copies of a single UHF algebra); among ASH algebras containing a non-trivial projection, we have only the UHF algebras of infinite type. It has been conjectured that  $\mathcal{Z}$  is the only strongly-self absorbing ASH algebra without non-trivial projections.

Recently, W. Winter proved that simple separable unital ASH algebras which are  $\mathcal{Z}$ -stable and in which projections separate traces satisfy the classification conjecture of G. Elliott ([20]). Explicitly, isomorphisms between the graded ordered  $K$ -groups of such  $C^*$ -algebras can be lifted to isomorphisms between the  $C^*$ -algebras. It is known that a strongly-self absorbing  $C^*$ -algebra is always infinitely self-absorbing, and that it has a unique tracial state whenever it is stably finite. Thus, using Theorem 1.1 and the fact that projections trivially separate traces in a unique trace  $C^*$ -algebra, we see that Winter's result applies to strongly self-absorbing ASH algebras. Such an algebra, when projectionless, has the same  $K$ -theory as  $\mathcal{Z}$ , and so is isomorphic to  $\mathcal{Z}$  by Winter's theorem. In other words,  $\mathcal{Z}$  is, as conjectured, the only strongly self-absorbing ASH algebra without non-trivial projections, and this completes the classification of strongly self-absorbing ASH algebras. We note, lest the reader find this last result too specialised, that there are no known examples of simple

unital separable amenable stably finite  $C^*$ -algebras which are not ASH, and that every stably finite strongly self-absorbing  $C^*$ -algebra is simple, separable, unital, and amenable.

The sequel is organised as follows: Section 2 introduces some notation pertaining to finite-dimensional representations of dimension drop algebras; Section 3 examines the homotopy groups of finite-dimensional representations of dimension drop algebras; Section 4 provides a continuous selection theorem for sub-representations of a semi-continuous field of representations of a dimension drop algebra over a compact Hausdorff space; in Section 5 we prove an extension theorem for certain maps out of dimension drop algebras; Section 6 combines our technical results to prove Theorem 1.1; in Section 7 we make some final remarks.

## 2. PRELIMINARIES AND NOTATION.

**2.1. Basic assumptions.** Unless otherwise noted, all morphisms in this paper are  $*$ -preserving algebra homomorphisms. We use  $M_k$  to denote the  $C^*$ -algebra of  $k \times k$  matrices with complex entries. If  $X$  is a compact Hausdorff space, then  $C(X)$  denotes the  $C^*$ -algebra of continuous complex-valued functions on  $X$ . If  $A$  is a unital  $C^*$ -algebra, then  $\mathcal{U}(A)$  is its unitary group.

**2.2. Finite-dimensional representations of dimension drop algebras.** We assume throughout that  $p$  and  $q$  are relatively prime integers strictly greater than one. The prime dimension drop algebra  $I_{p,q}$  is defined as follows:

$$I_{p,q} = \{f \in C([0, 1]; M_p \otimes M_q) \mid f(0) \in M_p \otimes 1_q, f(1) \in 1_p \otimes M_q\},$$

with the usual pointwise operations.

For any  $t \in [0, 1]$ , we define a  $*$ -homomorphism  $ev_t : I_{p,q} \rightarrow M_{pq} \cong M_p \otimes M_q$  by setting  $ev_t(f) = f(t)$ . If  $t \in (0, 1)$ , then we will refer to  $ev_t$  as a *generic evaluation*. Now suppose that  $f(0) = a \otimes 1_q$  and  $f(1) = 1_p \otimes b$ . Define maps  $e_0 : I_{p,q} \rightarrow M_p$  and  $e_1 : I_{p,q} \rightarrow M_q$  by  $e_0(f) = a$  and  $e_1(f) = b$ . We will refer to  $e_0$  and  $e_1$  as *endpoint evaluations*. Set  $F^k = \text{Hom}_1(I_{p,q}; M_k)$ . It is known that every integer  $k \geq pq - p - q$  can be written as a nonnegative integral linear combination of  $p$  and  $q$ , whence  $F^k$  is not empty in that case. Each  $\phi \in F^k$  is unitarily equivalent to

$$\tilde{\phi} = \left( \bigoplus_{i=1}^{a_\phi} e_0 \right) \oplus \left( \bigoplus_{k=1}^{b_\phi} e_1 \right) \oplus \left( \bigoplus_{j=1}^{c_\phi} ev_{x_j} \right),$$

where  $x_j \in (0, 1)$ . Let us denote by  $\text{sp}(\phi)$  the multiset consisting of the  $x_j$ s.

**2.3. Spectral multiplicity.** Let  $X$  be a compact Hausdorff space, and let

$$\phi : I_{p,q} \rightarrow C(X) \otimes M_k$$

be a unital  $*$ -homomorphism. If  $Y \subseteq X$ , then  $\phi|_Y$  will denote the restriction of  $\phi$  to  $Y$ . This restriction is actually a  $*$ -homomorphism into  $C(Y) \otimes M_k$  whenever  $Y$  is closed, and is

always at least a  $*$ -preserving algebra homomorphism into the set of continuous  $M_k$ -valued functions on  $Y$ .

We define  $N_0^\phi : X \rightarrow \mathbb{Z}^+$  (resp.  $N_1^\phi : X \rightarrow \mathbb{Z}^+$ ) to be the upper semicontinuous function which, at  $x \in X$ , returns the number of  $e_0$ s (resp.  $e_1$ s) occurring as direct summands of  $\phi|_{\{x\}}$ . Similarly, we define  $N_g^\phi : X \rightarrow \mathbb{Z}^+$  to be the lower semicontinuous function which, at  $x \in X$ , returns the number of generic evaluations occurring as direct summands of  $\phi|_{\{x\}}$ . These functions are related as follows:

$$(1) \quad k = pN_0^\phi(x) + qN_1^\phi(x) + pqN_g^\phi(x), \quad \forall x \in X.$$

### 3. REDUCING THE NUMBER OF GENERIC REPRESENTATIONS

Let  $F_l^k$  denote the subset of  $F^k$  consisting of those  $\phi$  for which  $\text{sp}(\phi)$  contains at most  $l$  points, counted with multiplicity. It follows that the difference  $F_l^k \setminus F_{l-1}^k$  consists of those  $\phi$  for which  $\text{sp}(\phi)$  contains exactly  $l$  points, counted with multiplicity. Let  $a$  and  $b$  be nonnegative integers satisfying

$$ap + bq + lpq = k.$$

Let  $F^k(a, b, l)$  denote the set of  $\phi \in F_l^k \setminus F_{l-1}^k$  which, up to unitary equivalence, contain exactly  $a$  direct summands of the form  $e_0$  and  $b$  direct summands of the form  $e_1$ . For a fixed  $l$ , the various  $F^k(a, b, l)$  are clopen subsets of  $F_l^k \setminus F_{l-1}^k$ . Finally, let  $S^k(a, b, l)$  denote the subset of  $F^k(a, b, l)$  consisting of those  $\phi$  which contain exactly  $l$  summands of the form  $ev_{1/2}$ .

**Lemma 3.1.** *The inclusion*

$$F_{l-1}^k \xrightarrow{\iota} F_{l-1}^k \cup F^k(a, b, l) \setminus S^k(a, b, l)$$

*is a deformation retract.*

*Proof.* Define a family  $\{h_t\}_{t \in [0, 1/2]}$  of continuous self-maps of  $[0, 1]$  as follows:

$$h_t(x) = \begin{cases} 0, & x \in [0, t] \\ (x - t)/(1 - 2t), & x \in (t, 1 - t) \\ 1, & x \in [1 - t, 1] \end{cases}.$$

Note that  $(x, t) \mapsto h_t(x)$  is continuous in both variables. Since  $h_t$  fixes 0 and 1, it induces an endomorphism  $\eta_t$  of  $I_{p,q}$  by acting on  $\text{Spec}(I_{p,q}) \cong [0, 1]$ .

Let us now define a continuous map

$$d : F_{l-1}^k \cup F^k(a, b, l) \setminus S^k(a, b, l) \rightarrow [0, 1/2].$$

On  $F_{l-1}^k$ , set  $d = 0$ . On  $F^k(a, b, l) \setminus S^k(a, b, l)$ ,  $d$  is the Hausdorff distance between the following two subsets of  $[0, 1]$ : first, the (nonempty) set of points in  $\text{sp}(\phi)$  which also lie in  $(0, 1/2) \cup (1/2, 1)$ ; second, the set  $\{0, 1\}$ .

Define a homotopy  $H(t)$  of self-maps of  $F_{l-1}^k \cup F^k(a, b, l) \setminus S^k(a, b, l)$  by

$$H(t)(\phi) = \phi \circ \eta_{td(\phi)}.$$

Since  $d(\phi) \equiv 0$  on  $F_{l-1}^k$  and  $\eta_0 = \mathbf{id}_{I_{p,q}}$ , we have

$$H(t)|_{F_{l-1}^k} = \mathbf{id}_{F_{l-1}^k}$$

and

$$H(0) = \mathbf{id}_{F_{l-1}^k \cup F^k(a, b, l) \setminus S^k(a, b, l)}.$$

Since  $\phi \circ \eta_{d(\phi)} \in F_{l-1}^k$  whenever  $\phi \in F^k(a, b, l) \setminus S^k(a, b, l)$ ,  $\iota$  is a deformation retract.  $\square$

**Proposition 3.2.** *The topological space  $F^k(a, b, l)$  can be endowed with the structure of a smooth manifold; the subspace  $S^k(a, b, l)$  is then a compact submanifold of codimension  $l^2$ .*

*Proof.* Note that  $M = \{\varphi : \text{Hom}(C[0, 1], M_l) : \text{Sp}(\varphi) \subset (0, 1)\}$  can be naturally identified with the set of all selfadjoint matrices in  $M_l$  having all their eigenvalues in  $(0, 1)$  and hence  $M$  is homeomorphic to  $\mathbb{R}^{l^2}$ .

We are going to exhibit a free, proper and smooth right action of the compact Lie group  $G = U(a) \times U(b) \times U(l)$  on the manifold  $X = M \times U(k) \cong \mathbb{R}^{l^2} \times U(k)$ , such that the quotient space is homeomorphic to  $F^k(a, b, l)$ . Then we invoke a result from [15] to conclude that  $X/G$  and hence  $F^k(a, b, l)$  admits a unique smooth structure for which the quotient map is a submersion. The uniqueness part of the same result shows that if  $Y$  is a  $G$ -invariant submanifold of  $X$ , then  $Y/G$  is a submanifold of  $X/G$ .

If  $\varphi \in M$ , then  $\varphi \otimes \text{id}_{pq} : C[0, 1] \otimes M_{pq} \rightarrow M_l \otimes M_{pq}$  defines by restriction a morphism on  $I_{p,q} \subset C[0, 1] \otimes M_{pq}$ . Let us define a continuous map  $P : M \times U(k) \rightarrow F^k(a, b, l)$  by

$$P(\varphi, u)(f) = u[(e_0(f) \otimes 1_a) \oplus (e_1(f) \otimes 1_b) \oplus (\varphi \otimes \text{id}_{pq})(f)]u^*,$$

where for  $f \in I_{p,q}$ ,  $f(0) = e_0(f) \otimes 1_q \in M_p \otimes M_q$  and  $f(1) = 1_p \otimes e_1(f) \in M_p \otimes M_q$ .

One verifies that the map  $P$  is surjective and that  $P(\varphi, u) = P(\psi, v)$  if and only if there is  $W = (w_0, w_1, w) \in G$  such that  $\psi = w^* \varphi w$  and  $v = u j(W)$  where  $j : G \rightarrow U(k)$  is the injective morphism

$$j(w_0, w_1, w) = (1_p \otimes w_0) \oplus (1_q \otimes w_1) \oplus (w \otimes 1_{pq}),$$

induced by the embedding of  $C^*$ -algebras

$$B = (1_p \otimes M_a) \oplus (1_q \otimes M_b) \oplus (M_l \otimes 1_{pq}) \subset M_k.$$

This shows that if we define a right action of  $G$  on  $X = M \times U(k)$  by

$$(\varphi, u)W = (w^* \varphi w, v j(W)),$$

where  $W = (w_0, w_1, w) \in U(a) \times U(b) \times U(l) = G$ , then  $P$  induces a continuous bijection  $X/G \rightarrow F^k(a, b, l)$ . This induced map is actually a homeomorphism since one can verify that  $P$  is an open map as follows. Fix  $(\varphi, u)$  in  $X$  and let  $V$  be a neighborhood of  $(\varphi, u)$ . We need to show that if  $P(\psi, v)$  is sufficiently close to  $P(\varphi, u)$ , then there is  $(\psi_1, v_1)$  in  $V$

such that  $P(\psi_1, v_1) = P(\psi, v)$ . Fix a metric  $d$  for the point-norm topology of  $F^k$ . Suppose that  $d(P(\varphi, u), P(\psi, v)) < \delta$  for some  $\delta > 0$  to be specified later. Then  $v^*u$  approximately commutes with the unit ball of the subalgebra  $A = (M_p \otimes 1_a) \oplus (M_q \otimes 1_b) \oplus (M_l \otimes 1_{pq})$  of  $M_k$ . By a classical perturbation result for finite dimensional  $C^*$ -algebras, there is a unitary  $z$  in the relative commutant of  $A$  in  $M_k$ ,  $z \in U(A' \cap M_k) = U(B)$  such that  $\|v^*u - z\| < g(\delta)$ , where  $g$  is a universal positive map with converges to 0 when  $\delta \rightarrow 0$ . We can write  $z = j(W)$  where  $W = (w_0, w_1, w) \in U(a) \times U(b) \times U(l)$ , as above. Let us set  $\psi_1 = w^*\psi w$  and  $v_1 = vj(W)$ . Then  $P(\psi_1, v_1) = P(\psi, v)$  and if  $\delta$  is chosen sufficiently small, then  $(\psi_1, v_1)$  is in  $V$  since  $\|u - vj(W)\| < g(\delta)$  and since  $d(w^*\psi w, \varphi) \rightarrow 0$  as  $\delta \rightarrow 0$ , because  $d(P(\varphi, 1), P(\psi, u^*v)) < \delta$ .

Having established the homeomorphism  $F^k(a, b, l) \cong X/G$ , we need to argue that  $X/G$  is a smooth manifold. To this purpose we apply Proposition 5.2 on page 38 of [15], according to which  $X/G$  is a manifold provided that  $X$  is a manifold and the action of the Lie group  $G$  on  $X$  is proper, free and smooth. Recall that a free right action  $G \times X \rightarrow X$  is proper if

- (1) The set  $C = \{(x, xg) : x \in X, g \in G\}$  is closed in  $X \times X$  and
- (2) The map  $\iota : C \rightarrow G$ ,  $\iota(x, xg) = g$  is continuous.

The first condition is easily verified if  $G$  is compact as shown in the last part of the proof of Proposition 3.1 on page 23 of [15]. To verify the second condition suppose that  $(x_n, x_n g_n)$  converges to  $(x, xg)$  in  $X \times X$ . Then  $x_n$  converges to  $x$  and hence  $\text{dist}(xg_n, x_n g_n) = d(x, x_n)$  converges to zero. It follows that  $xg_n$  converges to  $xg$ . If  $u$  is the component of  $x$  in  $U(k)$ , then  $uj(g_n)$  converges to  $uj(g)$  in  $U(k)$ . Therefore  $g_n$  must converge to  $g$ .

In conclusion  $F^k(a, b, l)$  is a manifold of dimension equal to  $\dim(X) - \dim(G) = l^2 + k^2 - (a^2 + b^2 + l^2)$ .

On the other hand,  $S^k(a, b, l)$  is the image in the quotient space  $X/G$  of the  $G$ -invariant submanifold  $\{\mu\} \times U(k)$  of  $X = M \times U(k)$ , where  $\mu(f) = f(1/2) \otimes 1_l$ . By applying [15, Prop. 5.2] once more we deduce that  $S^k(a, b, l)$  is a submanifold of  $F^k(a, b, l)$  of dimension  $k^2 - (a^2 + b^2 + l^2)$  and hence of codimension  $l^2$ .  $\square$

**Proposition 3.3.** *The inclusion  $F_{l-1}^k \hookrightarrow F_l^k$  is an  $(l^2 - 1)$ -equivalence.*

*Proof.* All manifolds in this proof are assumed to be metrisable and separable. Let  $S_l^k$  be the union of all  $S^k(a, b, l)$ . Let  $X$  be a smooth manifold of dimension  $\leq l^2 - 1$  and let  $Y$  be a compact subset of  $X$ . Let  $f : X \rightarrow F_l^k$  be a continuous map such that  $f(Y) \cap S_l^k = \emptyset$  and let  $\varepsilon > 0$ . We are going to show that there is a continuous map  $g : X \rightarrow F_l^k$  such that

- (i)  $d(f(x), g(x)) < \varepsilon$ , for all  $x \in X$ ,
- (ii)  $g = f$  on  $Y$ ,
- (iii)  $g(X) \cap S_l^k = \emptyset$ .

We shall apply this perturbation result in the realm of cellular maps from a pair of CW-complexes,  $(X, Y) = (S^n, *)$  or  $(X, Y) = (S^n \times [0, 1], \{*\} \times [0, 1])$  to the CW-complex  $F_l^k$ . This implies that  $f$  is homotopic to  $g$  via a homotopy that is constant on  $Y$ , assuming

that  $\varepsilon$  was chosen sufficiently small. Consequently, the inclusion

$$F_l^k \setminus S_l^k \hookrightarrow F_l^k$$

is an  $l^2 - 1$  equivalence. One concludes the proof by combining this fact with Lemma 3.1

Let us turn to the proof of the perturbation result. Note that  $S_l^k$  is a compact submanifold of  $F_l^k \setminus F_{l-1}^k$  and the latter is an open subset of  $F_l^k$ . We may assume that  $f^{-1}(S_l^k) \neq \emptyset$ , for otherwise there is nothing to prove. By a classical approximation result, we may assume that  $f$  is smooth on the pre-image  $f^{-1}(U)$  of some open neighborhood  $U$  of  $S_l^k$  in  $F_l^k \setminus F_{l-1}^k$ . After shrinking  $U$ , if necessary, we can arrange that  $U \cap f(Y) = \emptyset$  since  $f(Y) \cap S_l^k = \emptyset$ . Choose a smaller open neighborhood  $V$  of  $S_l^k$  such that  $\bar{V} \subset U$ .

Let  $f_1 : f^{-1}(U) \rightarrow U$  be the restriction of  $f$  to the manifold  $f^{-1}(U)$ . Note that  $f_1(f^{-1}(U \setminus V))$  is disjoint from  $S_l^k$  by construction. By Thom's transversality theorem [5, p. 557], since  $\dim(f^{-1}(U)) \leq l^2 - 1$  and  $S_l^k$  has codimension  $l^2$  in  $U$ , there is a smooth map  $g_1 : f^{-1}(U) \rightarrow U$  such that the image of  $g_1$  is disjoint from  $S_l^k$  and  $g_1 = f_1$  on the closed subset  $f^{-1}(U \setminus V)$  of  $f^{-1}(U)$  and  $d(f_1(x), g_1(x)) < \varepsilon$  for all  $x \in f^{-1}(U)$ . Then, the map  $g$  obtained by gluing  $g_1$  with the restriction of  $f$  to  $f^{-1}(F_l^k \setminus \bar{V})$  along  $f^{-1}(U \setminus \bar{V})$  satisfies the conditions (i)-(iii) from above.  $\square$

#### 4. SELECTIONS UP TO HOMOTOPY

Let  $\psi : \mathbb{I}_{p,q} \rightarrow \mathbb{C}(X) \otimes \mathbb{M}_k$  be a unital  $*$ -homomorphism. Let us abuse notation slightly and write  $\psi_x$  for  $\psi|_{\{x\}}$ . Set

$$V_i = \{x \in X \mid N_1^\psi(x) = i\}$$

and

$$O_i = \{x \in X \mid N_1^\psi(x) < i + 1\} = \bigcup_{j=1}^i V_j.$$

(We will write  $V_{i,\psi}$  and  $O_{i,\psi}$  for  $V_i$  and  $O_i$ , respectively, whenever it is not clear that  $\psi$  is the  $*$ -homomorphism with respect to which  $V_i$  and  $O_i$  have been defined.) Note that  $O_i$  is open for each  $i$ .

Each  $\psi_x$  has the form

$$u \left( \gamma' \oplus \bigoplus_{i=1}^{N_1^\psi(x)} e_1 \right) u^*$$

for some  $u \in \mathcal{U}(\mathbb{M}_k)$ . Set

$$\psi_x^1 = u \left( \bigoplus_{i=1}^{N_1^\psi(x)} e_1 \right) u^*.$$

In words,  $\psi_x^1$  is the largest direct summand of  $\psi_x$  which factors through  $e_1$ . We may view  $\psi_x^1$  as a unital  $*$ -homomorphism from  $\mathbb{M}_q$  to  $\psi_x^1(1)\mathbb{M}_k\psi_x^1(1)$ . If  $Y \subset X$  is closed, then we

define  $\psi_Y^1 : I_{p,q} \rightarrow \text{Map}(Y; M_k)$  by

$$\psi_Y^1(a)(x) = \psi_x^1(a), \quad \forall x \in Y.$$

**Lemma 4.1.** *Let  $\psi : I_{p,q} \rightarrow C(X) \otimes M_k$  be a unital  $*$ -homomorphism, and let  $Y \subset X$  be closed. If  $N_1^\psi$  is constant on  $Y$ , then  $\psi_Y^1$  is a  $*$ -homomorphism from  $I_{p,q}$  into  $C(Y) \otimes M_k \cong C(Y; M_k)$  which factors through  $e_1$ .*

*Proof.* Since  $\phi_Y^1$  preserves pointwise operations by definition, we need only check that  $\psi_Y^1(a) \in C(Y) \otimes M_k$  for each  $a \in I_{p,q}$ . Using the fact that  $N_1^\psi$  is constant on  $Y$  and a compactness argument, we can find some  $0 < \delta < 1/2$  such that if  $ev_t$  is, up to unitary equivalence, a summand of  $\psi_x$  and  $x \in Y$ , then  $t \in (0, 1 - \delta)$ . Let  $\tilde{a} \in I_{p,q}$  be an element which is equal to  $a$  at  $1 \in \text{Spec}(I_{p,q})$  and which vanishes on  $[0, 1 - \delta] \subseteq \text{Spec}(I_{p,q})$ . Since both  $\psi_Y^1(a)$  and  $\psi(\tilde{a})|_Y$  depend only on the value of  $a$  at 1, we conclude that they are equal. Since  $\psi(\tilde{a})|_Y \in C(Y) \otimes M_k$ , this completes the proof.  $\square$

Let  $\{e_{ij}\}_{i,j=1}^q$  be a set of matrix units for  $M_q$ , so that  $\{\psi_x^1(e_{ij})\}_{i,j=1}^q$  is a set of matrix units for the image of  $\psi_x^1$ . Given a subprojection  $r$  of  $\psi_x^1(e_{11})$ , we can generate a direct summand of  $\psi_x^1$  as follows: for each  $i, j \in \{1, \dots, q\}$ , set  $f_{ij} = \psi_x^1(e_{i1})r\psi_x^1(e_{1j})$ ; notice that the  $f_{ij}$  form a set of matrix units, so that

$$\psi_x^1 = \psi_x^{\bar{r}} \oplus \psi_x^r$$

with  $\psi_x^r(e_{ij}) := f_{ij}$ . We will refer to the map  $\psi_x^r$  as the *direct summand of  $\psi_x^1$  generated by  $r$* . If  $Y \subset X$  is closed and  $r : Y \rightarrow M_k$  is a projection-valued function such that  $r(x) \leq \psi_x^1(e_{11})$  for every  $x \in Y$ , then we define  $\psi_Y^r : M_q \rightarrow \text{Map}(Y; M_k)$  by

$$\psi_Y^r(a)(x) = \psi_x^{r(x)}(a).$$

If  $Y$  satisfies the hypotheses of Lemma 4.1 and  $r$  is continuous, then  $\psi_Y^r$  defines a unital  $*$ -homomorphism from  $M_q$  into a corner of  $(C(Y) \otimes M_k)$ .

Let  $h_t$  be the continuous self-map of  $[0, 1]$  introduced in the proof of Lemma 3.1, and let  $\eta_t$  be the induced endomorphism of  $I_{p,q}$ . Observe that  $(\psi \circ \eta_t)_x$  has fewer generic representations than  $\psi_x$ . Alternatively,

$$N_i^{\psi \circ \eta_t}(x) \geq N_i^\psi(x), \quad \forall x \in X, \quad t \in [0, 1/2], \quad i \in \{0, 1\}.$$

Also note that  $\psi \circ \eta_t$  is homotopic to  $\psi$  for each  $t \in [0, 1/2]$ . Since  $h_t$  fixes 1, we have that

$$(2) \quad (\psi \circ \eta_t)_x^1 = \psi_{x,t}^1 \oplus \psi_x^1,$$

for some suitable  $*$ -homomorphism  $\psi_{x,t}^1$  which factors through  $e_1$ . Also, for any  $0 \leq t < s < 1/2$  we have that

$$(3) \quad \overline{O_{i,(\psi \circ \eta_s)}} \subseteq O_{i,(\psi \circ \eta_t)}.$$

Inspection of the definition of  $h_t$  shows that  $h_t \circ h_s = h_{s'}$  for some  $s' \in [0, 1/2]$ .

**Lemma 4.2.** *Let  $\psi : I_{p,q} \rightarrow C(X) \otimes M_k$  be a unital  $*$ -homomorphism, and let  $i \in \{1, \dots, \lfloor k/q \rfloor - 1\}$  be given. Suppose that the following statements hold:*

- (i) *there is a continuous and constant rank projection-valued map*

$$Q : \overline{O_{i,\psi}} \rightarrow M_k$$

*corresponding to a trivial vector bundle ( $O_{i,\psi}$  is assumed to be nonempty);*

- (ii) *for each  $x \in \overline{O_{i,\psi}}$ ,*

$$Q(x) \leq \psi_x^1(e_{11})$$

*and*

$$\text{rank}(Q(x)) + 2\dim(X) \leq \text{rank}(\psi_x^1(e_{11}));$$

- (iii) *the map  $\psi_{\overline{O_{i,\psi}}}^{Q(x)}$  defines a  $*$ -homomorphism from  $M_q$  to  $C(\overline{O_{i,\psi}}) \otimes M_k$ .*

*Then, there is a unital  $*$ -homomorphism  $\gamma : I_{p,q} \rightarrow C(X) \otimes M_k$  homotopic to  $\psi$  such that the following statements hold:*

- (i) *there is a continuous and constant rank projection-valued map*

$$\tilde{Q} : \overline{O_{i+1,\gamma}} \cup \overline{O_{i,\psi}} \rightarrow M_k$$

*which corresponds to a trivial vector bundle and extends the function  $Q$  above;*

- (ii) *for each  $x \in \overline{O_{i+1,\gamma}} \cup \overline{O_{i,\psi}}$ ,*

$$\tilde{Q}(x) \leq \gamma_x^1(e_{11})$$

*and*

$$\text{rank}(\tilde{Q}(x)) + 2\dim(X) \leq \text{rank}(\gamma_x^1(e_{11}));$$

- (iii) *the map  $\tilde{\phi} : M_q \rightarrow \text{Map}(\overline{O_{i+1,\gamma}} \cup \overline{O_{i,\psi}}; M_k)$  which agrees with  $\psi_{\overline{O_{i,\psi}}}^{Q(x)}$  on  $\overline{O_{i,\psi}}$  and is equal to  $\gamma_x^{\tilde{Q}(x)}$  otherwise is in fact equal to  $\gamma_{\overline{O_{i+1,\gamma}} \cup \overline{O_{i,\psi}}}^{\tilde{Q}(x)}$ , and is a  $*$ -homomorphism into  $C(\overline{O_{i+1,\gamma}} \cup \overline{O_{i,\psi}}) \otimes M_k$ .*

*Proof.* Choose  $t \in (0, 1/2)$ , and set  $\gamma = \psi \circ \eta_t$ . This ensures that  $\psi$  and  $\gamma$  are homotopic. Note that  $A := \overline{O_{i+1,\gamma}} \setminus O_{i,\psi}$  is closed in  $X$ , and that  $Q$  is already defined on  $O_{i,\psi}$ . The task of extending  $Q$  to  $\tilde{Q}$  is thus reduced to the problem of extending  $Q|_{A \cap \overline{O_{i,\psi}}}$  to all of  $A$  and proving that our extension satisfies (i), (ii), and (iii) in the conclusion of the lemma.

Any constant rank extension of  $Q|_{A \cap \overline{O_{i,\psi}}}$  to all of  $A$  will automatically satisfy the rank requirement in conclusion (ii). So, to begin, let us extend  $Q|_{A \cap \overline{O_{i,\psi}}}$  to a trivial constant rank projection  $\tilde{Q}$  defined on all of  $A$  and subordinate to  $\gamma_x^1(e_{11})$  at each  $x \in A$ . For each  $x \in A$ , we have that

$$(4) \quad \text{rank}(\gamma_x^1(e_{11})) \geq \text{rank}(\psi_x^1(e_{11})) \geq 2\dim(X) + \text{rank}(Q).$$

By (3),  $A$  is a closed subset of  $V_{i+1} = O_{i+1,\psi} \setminus O_{i,\psi}$ . In particular, the rank of  $\psi_x^1(e_{11})$  is constant on  $A$ , and  $x \mapsto \psi_x^1(e_{11})$  is a continuous and constant rank projection valued function on  $A$ , call it  $R(x)$ . Moreover,  $Q(x) \leq R(x) \leq \gamma_x^1(e_{11})$  for each  $x \in A \cap \overline{O_{i,\psi}}$ . It

is a general fact that  $Q|_{A \cap \overline{O_{i,\psi}}}$  can be extended to a trivial projection defined on  $A$  and subordinate to  $R$ , as desired—all that is required for this is the rank inequality of (4). Our  $\tilde{Q}$  thus satisfies parts (i) and (ii) in the conclusion of the lemma.

Let us now establish part (iii) in the conclusion of the lemma. Observe that at each point in  $X$ ,  $\gamma_x^1$  decomposes as the direct sum of  $\psi_x^1$  and a second morphism, say  $\lambda$  (cf. (2) above). Also recall that  $Q(x) = \tilde{Q}(x)$  for each  $x \in A \cap \overline{O_{i,\psi}}$ . It follows that for any  $x \in A \cap \overline{O_{i,\psi}}$  and  $i, j \in \{1, \dots, q\}$ , we have

$$\begin{aligned} \gamma_x^{\tilde{Q}(x)}(e_{ij}) &= \gamma_x^1(e_{i1})\tilde{Q}(x)\gamma_x^1(e_{1j}) \\ &= (\psi_x^1(e_{i1}) \oplus \lambda(e_{i1}))Q(x)(\psi_x^1(e_{1j}) \oplus \lambda(e_{1j})) \\ &= \psi_x^1(e_{i1})Q(x)\psi_x^1(e_{1j}) \\ &= \psi_x^{Q(x)}(e_{ij}), \end{aligned}$$

and so

$$\gamma_x^{\tilde{Q}(x)} = \gamma_x^{Q(x)} = \psi_x^{Q(x)}, \quad \forall x \in A \cap \overline{O_{i,\psi}}.$$

Our problem is thus reduced to proving that  $\gamma_A^{\tilde{Q}}$  is a  $*$ -homomorphism from  $M_q$  into  $C(A) \otimes M_k$ . In a near repeat of our calculation above we have

$$\begin{aligned} \gamma_x^{\tilde{Q}(x)}(e_{ij}) &= \gamma_x^1(e_{i1})\tilde{Q}(x)\gamma_x^1(e_{1j}) \\ &= (\psi_x^1(e_{i1}) \oplus \lambda(e_{i1}))\tilde{Q}(x)(\psi_x^1(e_{1j}) \oplus \lambda(e_{1j})) \\ &= \psi_x^1(e_{i1})\tilde{Q}(x)\psi_x^1(e_{1j}) \\ &= \psi_x^{\tilde{Q}(x)}(e_{ij}); \end{aligned}$$

$\psi_x^{\tilde{Q}(x)}(e_{1j})$  is defined because  $\tilde{Q}(x) \leq R(x) \equiv \psi_x^1(e_{11})$  by construction. We conclude that  $\psi_A^{\tilde{Q}} = \gamma_A^{\tilde{Q}}$ . Since  $A \subseteq V_{i+1}$ , the function  $N_1^\psi$  is constant on  $A$ . It now follows from Lemma 4.1 that  $\psi_A^{\tilde{Q}}$  is a  $*$ -homomorphism, completing the proof.  $\square$

**Proposition 4.3.** *Let  $X$  be a compact metric space of covering dimension  $d < \infty$ , and let  $\psi : I_{p,q} \rightarrow C(X) \otimes M_k$  be a unital  $*$ -homomorphism. Suppose that  $N_1^\psi(x) > 2d$  for each  $x \in X$ , and let  $m$  be the minimum value taken by  $N_1^\psi$  on  $X$ . Then,  $\psi$  is homotopic to a unital  $*$ -homomorphism  $\gamma : I_{p,q} \rightarrow C(X) \otimes M_k$  with the following property:  $\gamma$  can be decomposed as a direct sum  $\eta \oplus \phi$ , where  $\phi$  is unitarily equivalent to*

$$\bigoplus_{j=1}^{m-2d} e_1$$

inside  $C(X) \otimes M_k$ .

*Proof.* We will proceed by iterating Lemma 4.2. First, we require some initial data satisfying the hypotheses of the said lemma. Suppose that  $O_{j,\psi}$  is empty for  $0 \leq j \leq i$ , and

that  $O_{i+1,\psi}$  is not empty. It follows that for some choice of  $t \in (0, 1/2)$ , the morphism  $\Delta := \psi \circ \eta_t$  has  $O_{i+1,\Delta}$  nonempty. Since  $O_{i,\psi}$  is empty, we have that

$$V_{i+1,\psi} = O_{i+1,\psi} \supseteq \overline{O_{i+1,\Delta}}.$$

In particular,  $N_1^\psi$  is constant on  $\overline{O_{i+1,\Delta}}$ , and so  $\psi|_{\overline{O_{i+1,\Delta}}}$  is a  $*$ -homomorphism. The map  $x \mapsto \psi_x^1(e_{11})$  is continuous and projection-valued on  $\overline{O_{i+1,\Delta}}$ . Using the stability properties of vector bundles, we may find a continuous and projection-valued map  $Q : \overline{O_{i+1,\Delta}} \rightarrow M_k$  which is subordinate to  $\phi_x^1(e_{11})$  at each  $x \in \overline{O_{i+1,\Delta}}$ , has constant rank equal to  $m - 2d$ , and corresponds to a trivial vector bundle. The maps  $\Delta$ ,  $Q$ , and  $\Delta|_{\overline{O_{i+1,\Delta}}}^Q$  thus constitute acceptable initial data for Lemma 4.2.

Notice that in part (iii) of the conclusion of Lemma 4.2, we may replace the set  $\overline{O_{i+1,\gamma}} \cup \overline{O_{i,\psi}}$  with the smaller set  $\overline{O_{i+1,\gamma}}$ . Beginning with the initial data constructed above, we iterate this modified version of Lemma 4.2 as many times as is necessary in order to arrive at a  $*$ -homomorphism  $\gamma$ , homotopic to  $\psi$  by construction, which has the property that  $O_{l+1,\gamma} = X$ . This map has the desired direct summand  $\phi$  upon restriction to  $\overline{O_{l,\gamma}}$ , as provided by part (iii) in the conclusion of Lemma 4.2. In order to extend  $\phi$  to all of  $X$ , simply follow the proof of Lemma 4.2 with  $A := O_{l+1,\gamma} \setminus O_{l,\gamma} = V_{l+1,\gamma}$ . The proof works because this choice of  $A$  is closed.

The unitary equivalence of  $\phi$  with

$$\bigoplus_{j=1}^{m-2d} e_1$$

follows from two facts: first, the images of the projections  $e_{11}, e_{22}, \dots$  under  $\phi$  all correspond to trivial vector bundles by construction; second, the complement of the sum of these images has rank larger than  $d$  and the same  $K_0$ -class as a trivial vector bundle, whence it is unitarily equivalent to any projection corresponding to a trivial vector bundle of the same rank.  $\square$

**Remark 4.4.** By replacing 1 with 0 and  $p$  with  $q$  in this subsection, Proposition 4.3 can be restated with  $N_0^\psi$  substituted for  $N_1^\psi$  and  $e_0$  substituted for  $e_1$ . This fact will be used in the proof of the Lemma 4.5 below.

**Lemma 4.5.** *Let  $X$  be a compact metric space of covering dimension  $d < \infty$ . Let there be given a unital  $*$ -homomorphism  $\phi : I_{p,q} \rightarrow C(X) \otimes M_k$  with the property that  $N_g^\phi < L$  on  $X$  for some  $L > 2d$ . Assume that  $k > (2L + 2d + 1)pq$ . It follows that  $\phi$  is homotopic to a second morphism  $\psi$  with the property that*

$$N_1^\psi \geq \left\lfloor \frac{k - 2pq(L + d)}{q} \right\rfloor.$$

*Proof.* Since  $N_0^\phi$  is upper semicontinuous, the set

$$F_z^\phi := \{x \in X \mid N_0^\phi(x) \geq z\}$$

is closed for every  $z \in \mathbb{Z}^+$ . We also have that  $F_z^\phi \subseteq F_{z'}^\phi$  whenever  $z \geq z'$ .

**Claim 1:**  $F_{z+qL}^\phi$  is contained in the interior of  $F_z^\phi$ .

*Proof of claim.* Let  $x \in F_{z+qL}$ . By the upper semicontinuity of  $N_0^\phi$  and  $N_1^\phi$ , there is a neighborhood  $V$  of  $x$  such that  $N_0^\phi(x) - N_0^\phi(v) \geq 0$  and  $N_1^\phi(x) - N_1^\phi(v) \geq 0$  for all  $v \in V$ . Using (1) and the assumption that  $N_g^\phi < L$  we have that

$$\begin{aligned} p(N_0^\phi(x) - N_0^\phi(v)) &\leq p(N_0^\phi(x) - N_0^\phi(v)) + q(N_1^\phi(x) - N_1^\phi(v)) \\ &= pq(N_g^\phi(v) - N_g^\phi(x)) < pqL \end{aligned}$$

for all  $v \in V$ . It follows that  $N_0^\phi(v) > N_0^\phi(x) - qL \geq z + qL - qL = z$  and hence  $V \subset F_z^\phi$ .  $\square$

From the claim above we conclude that for each  $n \in \mathbb{N}$ , there is an open set  $U_{nqL}^\phi \subseteq X$  such that  $F_{nqL}^\phi \subseteq U_{nqL}^\phi \subseteq F_{(n-1)qL}^\phi$ .

Consider the following chain of inclusions:

$$F_{qL}^\phi \supseteq U_{2qL}^\phi \supseteq F_{2qL}^\phi \supseteq U_{3qL}^\phi \supseteq F_{3qL}^\phi \supseteq \cdots$$

It follows from the definition of  $\eta_s$  that each  $x \in F_z^\phi$  is an interior point of  $F_z^{\phi \circ \eta_s}$  whenever  $s > 0$ . We may thus assume, by modifying  $U_{nqL}^\phi$  is necessary, that for some  $s_0 \in [0, 1/2)$  and each  $n \in \mathbb{N}$  we have

$$F_{nqL}^{\phi \circ \eta_{s_0}} \supseteq \overline{U_{nqL}^\phi} \supseteq U_{nqL}^\phi \supseteq F_{nqL}^\phi.$$

Set  $\phi_0 = \phi \circ \eta_{s_0}$ . Let us consider the finite set  $S$  consisting of those positive integers  $n$  such that  $nL > 2d$  and  $F_{nqL}^\phi \neq \emptyset$ . Since  $L > 2d$  by hypothesis, we have  $1 \in S$  whenever  $S$  is nonempty.

**Claim 2:** There is a  $t_0 \in [0, 1/2)$  such that the following statements hold for  $\phi' := \phi_0 \circ \eta_{t_0}$ :

(i) for every  $n \in S$ , the restriction  $\phi'|_{\overline{U_{nqL}^\phi}}$  has a direct summand of the form

$$\gamma_n := \bigoplus_{i=1}^{(nL-2d)q} e_0 = \bigoplus_{j=1}^{nL-2d} ev_0;$$

(ii)  $\gamma_n|_{\overline{U_{mqL}^\phi}}$  is a direct summand of  $\gamma_m$  whenever  $m > n$ .

*Proof of claim.* We proceed by induction on  $n$ . Let  $n = 1$ . Upon adjusting Proposition 4.3 according to Remark 4.4, we may apply it to  $\phi_0|_{\overline{U_{qL}^\phi}}$  and find a unital  $*$ -homomorphism

$$\phi_1 : \mathbf{I}_{p,q} \rightarrow C(\overline{U_{qL}^\phi}) \otimes M_k$$

homotopic to  $\phi_0|_{\overline{U_{qL}^\phi}}$  such that  $\phi_1$  has a direct summand of the form

$$\gamma_1 := \bigoplus_{i=1}^{(L-2d)q} e_0 = \bigoplus_{j=1}^{L-2d} ev_0.$$

The homotopy which arises in the proof of Proposition 4.3 comes from composing  $\phi_0|_{\overline{U_{qL}^\phi}}$  with a path of  $\eta_t$ s. This homotopy may be extended to all of  $X$  by composing  $\phi_0$  with the same path of  $\eta_t$ s, and so we may assume that  $\phi_1$  is defined on all of  $X$ .

Now let us suppose that we have found a unital  $*$ -homomorphism  $\phi_n : I_{p,q} \rightarrow C(X) \otimes M_k$  homotopic to  $\phi_0$  via composition with  $\eta_t$ s such that the following statements hold:

- (i) for every  $k \in \{1, \dots, n\} \subseteq S$ , the restriction  $\phi_n|_{\overline{U_{kqL}^\phi}}$  has a direct summand of the form

$$\gamma_k := \bigoplus_{i=1}^{(kL-2d)q} e_0 = \bigoplus_{j=1}^{kL-2d} ev_0;$$

- (ii)  $\gamma_k|_{\overline{U_{mqL}^\phi}}$  is a direct summand of  $\gamma_m$  whenever  $m > k$ .

Assuming that  $n+1 \in S$ , we will construct  $\phi_{n+1}$ , homotopic to  $\phi_n$  via composition with  $\eta_t$ s, such that the statements (i) and (ii) above hold with  $n$  replaced by  $n+1$ . Through successive applications of this inductive step we will arrive at the map  $\phi'$  required by the claim.

If  $\overline{U_{(n+1)qL}^\phi} = \emptyset$  then we simply put  $\phi' = \phi_n$ ; suppose that  $\overline{U_{(n+1)qL}^\phi} \neq \emptyset$ . Let  $p_n$  be the image of the unit of  $I_{p,q}$  under  $\gamma_n$ , restricted to  $\overline{U_{(n+1)qL}^\phi}$ . Applying Proposition 4.3 to the cut-down map

$$(1 - p_n)(\phi_n|_{\overline{U_{(n+1)qL}^\phi}})(1 - p_n),$$

we find a unital  $*$ -homomorphism

$$\phi_{n+1} : I_{p,q} \rightarrow C(\overline{U_{(n+1)qL}^\phi}) \otimes M_k$$

(which, as in the establishment of the base case, arises from composing  $\phi_n|_{\overline{U_{(n+1)qL}^\phi}}$  with some  $\eta_t$ ) admitting a direct summand

$$\alpha_{n+1} = \bigoplus_{i=1}^{Lq} e_0 = \bigoplus_{j=1}^L ev_0.$$

Define

$$\gamma_{n+1} = \alpha_{n+1} \oplus \gamma_n|_{\overline{U_{(n+1)qL}^\phi}}.$$

As before, we may extend the definition of  $\phi_{n+1}$  to all of  $X$ . These choices of  $\phi_{n+1}$  and  $\gamma_{n+1}$  establish the induction step of our argument, proving the claim.  $\square$

Set  $\alpha_1 = \gamma_1$ . Choose, for each  $n \in S$ , a continuous map  $g_n : \overline{U_{nqL}^\phi} \rightarrow [0, 1]$  with the property that  $g_n$  is identically zero off  $U_{nqL}^\phi$  and identically one on  $F_{nqL}^\phi$ . Notice that at any given  $x \in X$ , at most one of the  $g_n$ s defined at  $x$  can take a value other than one.

Define a homotopy  $H : [0, 1] \rightarrow \text{Hom}_1(I_{p,q}; C(X) \otimes M_k)$  as follows:

- (i)  $H(0) = \phi'$ .

- (ii) For  $t \in (0, 1]$ ,  $n$  such that  $\overline{U_{nqL}^\phi} \setminus \overline{U_{(n+1)qL}^\phi} \neq \emptyset$ , and  $x \in \overline{U_{nqL}^\phi} \setminus \overline{U_{(n+1)qL}^\phi}$ ,  $H(t)_x$  differs from  $\phi'_x$  as follows: with  $\gamma_n^\perp$  denoting the complement of  $\gamma_n$  inside  $\phi'_x|_{\overline{U_{nqL}^\phi}}$  we have

$$\begin{aligned} \phi'_x &= (\gamma_n^\perp)_x \oplus \bigoplus_{i=1}^n (\alpha_i)_x \\ &= (\gamma_n^\perp)_x \oplus (\oplus_{j=1}^{L-2d} ev_0) \oplus \underbrace{(\oplus_{j=1}^L ev_0) \oplus \cdots \oplus (\oplus_{j=1}^L ev_0)}_{n-1 \text{ times}}, \end{aligned}$$

where the summands of the form  $\oplus_{j=1}^L ev_0$  correspond, in order, to the  $(\alpha_i)_x$ s with  $i > 1$ ; on the other hand, modifying the second equation above, we set

$$H(t)_x = (\gamma_n^\perp)_x \oplus (\oplus_{j=1}^{L-2d} ev_{tg_1(x)}) \oplus (\oplus_{j=1}^L ev_{tg_2(x)}) \oplus \cdots \oplus (\oplus_{j=1}^L ev_{tg_n(x)}).$$

- (iii) for  $t \in (0, 1]$  and  $x \notin \overline{U_{qL}^\phi}$ , we set  $H(t)_x = \phi'_x$ .

To see that  $H(t)$  is a homotopy, one need only check the continuity of  $\overline{H(t)_x}$  at the boundary of  $\overline{U_{nqL}^\phi}$ . This amounts to checking that if  $x, y \in X$  are close and  $x \in \partial \overline{U_{nqL}^\phi}$ , then  $H(t)_x$  and  $H(t)_y$  are close. Each  $y$  sufficiently close to  $x$  is either in  $\overline{U_{nqL}^\phi} \setminus \overline{U_{(n+1)qL}^\phi}$  or  $\overline{U_{(n-1)qL}^\phi} \setminus \overline{U_{nqL}^\phi}$  by Claim 1, so we need only address this situation. If  $y \in \overline{U_{nqL}^\phi} \setminus \overline{U_{(n+1)qL}^\phi}$ , then  $H(t)_x$  and  $H(t)_y$  are close by part (ii) of the definition of  $H(t)$  and the fact that  $(\gamma_n^\perp)_x$  is continuous in  $x$  on  $\overline{U_{nqL}^\phi} \setminus \overline{U_{(n+1)qL}^\phi}$  (it is the complement of  $(\gamma_n)_x$ , and the latter is continuous in  $x$  on  $\overline{U_{nqL}^\phi} \setminus \overline{U_{(n+1)qL}^\phi}$  by construction). If, on the other hand,  $y \in \overline{U_{(n-1)qL}^\phi} \setminus \overline{U_{nqL}^\phi}$ , then we must check that

$$H(t)_x = (\gamma_n^\perp)_x \oplus (\oplus_{j=1}^{L-2d} ev_{tg_1(x)}) \oplus (\oplus_{j=1}^L ev_{tg_2(x)}) \oplus \cdots \oplus (\oplus_{j=1}^L ev_{tg_n(x)})$$

is close to

$$H(t)_y = (\gamma_{n-1}^\perp)_y \oplus (\oplus_{j=1}^{L-2d} ev_{tg_1(y)}) \oplus (\oplus_{j=1}^L ev_{tg_2(y)}) \oplus \cdots \oplus (\oplus_{j=1}^L ev_{tg_{n-1}(y)})$$

Since  $\oplus_{j=1}^L ev_{tg_k(x)}$  is continuous on  $\overline{U_{(n-1)qL}^\phi}$  for each  $k \in \{1, \dots, n-1\}$ , we need only check that  $(\gamma_n^\perp)_x \oplus (\oplus_{j=1}^L ev_{tg_n(x)})$  is close to  $(\gamma_{n-1}^\perp)_y$ . By the definition of  $g_n$ , we have  $g_n(x) = 0$ , so that

$$(\gamma_n^\perp)_x \oplus (\oplus_{j=1}^L ev_{tg_n(x)}) = (\gamma_n^\perp)_x \oplus (\oplus_{j=1}^L ev_0) = (\gamma_{n-1}^\perp)_x.$$

Our desired conclusion now follows from the continuity of  $\gamma_{n-1}^\perp$  on  $\overline{U_{(n-1)qL}^\phi}$ .

Put  $\psi = H(1)$ , so that  $\psi$  is homotopic to  $\phi$ , as required. To complete the proof of the lemma, we analyse the function  $N_1^\psi$ . The homotopy  $H$  leaves untouched those direct summands of  $\phi'_x$  of the form  $e_1$ , whence  $N_1^\psi \geq N_1^{\phi'}$ . By construction, we have that  $N_1^{\phi'}(x) \geq N_1^\phi(x)$  for each  $x \in X$ .

First consider the case  $S = \emptyset$ . (Note that this assumption implies  $F_{qL}^\phi = \emptyset$ .) It follows that  $N_0^\phi < qL$  on  $X$ . Using (1) we obtain the following for each  $x \in X$ :

$$\begin{aligned} qN_1^\phi(x) &= k - pN_0^\phi(x) - pqN_g^\phi(x) \\ &> k - pqL - pqL \geq k - 2pq(L + d). \end{aligned}$$

We conclude that

$$N_1^\psi(x) \geq N_1^{\phi'}(x) \geq N_1^\phi(x) > (k - 2pq(L + d))/q,$$

as desired.

Now suppose that  $S \neq \emptyset$  and write  $S = \{1, \dots, n\}$ . We have

$$X = X \setminus \overline{U_{qL}^\phi} \cup \left( \bigcup_{s=1}^{n-1} \overline{U_{sqL}^\phi \setminus U_{(s+1)qL}^\phi} \right) \cup \overline{U_{nqL}^\phi}.$$

Fix  $x \in X$ . In light of the partition of  $X$  above, we consider two cases, depending on whether or not  $x \in \overline{U_{qL}^\phi}$ .

First suppose that  $x \in X \setminus \overline{U_{qL}^\phi}$ . In this case the definition of the homotopy  $H$  implies that  $\psi_x = (\phi \circ \eta_t)_x$  for some  $t \in [0, 1]$ . By the spectral properties of  $\eta_t$  we conclude that  $N_1^\psi(x) \geq N_1^\phi(x)$ . From here, one simply applies the argument from the  $S = \emptyset$  case.

Second, suppose that  $x \in \overline{U_{sqL}^\phi \setminus U_{(s+1)qL}^\phi}$  for some  $s \in \{1, \dots, n\}$ , with the convention that  $\overline{U_{(n+1)qL}^\phi} = \emptyset$ . From the definition of the homotopy  $H$  we have

$$\begin{aligned} \psi_x &= \left[ (\gamma_s^\perp)_x \oplus (\oplus_{j=1}^{L-2d} ev_{tg_1(x)}) \oplus (\oplus_{j=1}^L ev_{tg_2(x)}) \oplus \dots \oplus (\oplus_{j=1}^L ev_{tg_s(x)}) \right]_{t=1} \\ &= (\gamma_s^\perp)_x \oplus \left( \bigoplus_{j=1}^{(s-1)L-2d} ev_1 \right) \oplus (\oplus_{j=1}^L ev_{g_s(x)}) \end{aligned}$$

(the last line follows from the fact that  $g_k$  is by definition identically one on

$$\overline{U_{sqL}^\phi} \subseteq F_{(s-1)qL}^\phi$$

whenever  $k \leq s-1$ ). By construction we have  $(\gamma_s^\perp)_x \oplus (\gamma_s)_x = (\phi \circ \eta_t)_x$  for some  $t \in [0, 1]$ . This, by the spectral properties of  $\eta_t$ , implies that

$$N_1^{(\gamma_s^\perp)_x \oplus (\gamma_s)_x}(x) \geq N_1^\phi(x).$$

All of the  $e_1$  summands of  $(\gamma_s^\perp)_x \oplus (\gamma_s)_x$  are contained in  $(\gamma_s^\perp)_x$ , so we conclude that  $N_1^{(\gamma_s^\perp)_x}(x) \geq N_1^\phi(x)$ . Combining this with our formula for  $\psi_x$  above, we have

$$(5) \quad N_1^\psi(x) \geq N_1^\phi(x) + p[(s-1)L - 2d].$$

Since  $F_{(s+1)qL}^\phi \subseteq \overline{U_{(s+1)qL}^\phi}$ , we have  $x \in X \setminus F_{(s+1)qL}^\phi$ . In particular,  $N_0^\phi(x) < (s+1)qL$ . Combining this last fact with (1) and the inequality  $N_g^\phi < L$  yields

$$N_1^\phi(x) > \frac{k - (s+2)pqL}{q}.$$

Combining the inequality above with (5) then yields

$$N_1^\psi(x) \geq \frac{k - (s+2)pqL}{q} + p(sL - 2d) = \frac{k - 2pq(L + d)}{q},$$

as desired. □

**Corollary 4.6.** *Let  $X$  be a compact metric space of covering dimension  $d < \infty$ . Let there be given a unital  $*$ -homomorphism  $\phi : \mathbb{I}_{p,q} \rightarrow C(X) \otimes M_k$  with the property that  $N_g^\phi < 2d+1$  on  $X$ . Assume that  $k > (8d+4)pq$ . It follows that  $\phi$  is homotopic to a second  $*$ -homomorphism  $\psi$  which has a direct summand of the form*

$$\bigoplus_{i=1}^M ev_{1/2},$$

where

$$M = \left\lfloor \frac{k - pq(8d+4)}{pq} \right\rfloor.$$

*Proof.* Apply Lemma 4.5 to  $\phi$  with  $L = 2d+1$ . This yields a map  $\phi'$  homotopic to  $\phi$  with the property that

$$N_1^{\phi'} \geq \left\lfloor \frac{k - 2pq(3d+1)}{q} \right\rfloor.$$

By our assumption on the size of  $k$  we have

$$m := \left\lfloor \frac{k - 2pq(3d+1)}{q} \right\rfloor > \lfloor (2d+2)p \rfloor.$$

Apply Proposition 4.3 to  $\phi'$  with  $m$  as above. This yields a map  $\phi''$  homotopic to  $\phi'$  which has a direct summand of the form  $\bigoplus_{i=1}^{m-2d} e_1$ . Straightforward calculation shows that

$$m - 2d \geq \left\lfloor \frac{k - pq(8d+3)}{q} \right\rfloor > \frac{k - pq(8d+4)}{q} \geq p \left\lfloor \frac{k - pq(8d+4)}{pq} \right\rfloor = pM.$$

The summand  $\bigoplus_{i=1}^{pM} e_1$  is clearly homotopic to  $\bigoplus_{i=1}^M ev_{1/2}$ , and the corollary follows. □

## 5. AN EXTENSION RESULT

We need the following corollary of [3, Cor. 4.6]

**Corollary 5.1.** *Let  $B$  be a separable, nuclear, unital, residually finite-dimensional  $C^*$ -algebra. Let  $(\pi_k)_{k=1}^\infty$  be a sequence of unital finite dimensional representations of  $B$  which separates the points of  $B$  and such that each representation occurs infinitely many times. For any unital  $C^*$ -algebra  $A$  and any two unital  $*$ -homomorphisms  $\alpha, \beta : B \rightarrow M_k(A)$  with  $KK(\alpha) = KK(\beta)$ , there is a sequence of unitaries  $u_n \in M_{k+r(n)}(A)$ , where  $r(n)$  is the rank of the projection  $(\pi_1 \oplus \cdots \oplus \pi_n)(1_B)$ , such that for all  $b \in B$*

$$\lim_{n \rightarrow \infty} \|u_n(\alpha(b) \oplus \pi_1(b) \oplus \cdots \oplus \pi_n(b))u_n^* - \beta(b) \oplus \pi_1(b) \oplus \cdots \oplus \pi_n(b)\| = 0.$$

For a finite dimensional representation  $\pi : B \rightarrow M_k$ , the induced  $*$ -homomorphism  $\pi \otimes 1_A : B \rightarrow M_k(A)$ ,  $b \mapsto \pi(b) \otimes 1_A$  was also denoted by  $\pi$  in the statement above.

**Proposition 5.2.** *Let  $p$  and  $q$  be relatively prime integers strictly greater than one. There exists a constant  $K \in \mathbb{N}$  such that the following holds: for any unital  $C^*$ -algebra  $A$  and unital  $*$ -homomorphisms  $\psi, \gamma : I_{p,q} \rightarrow A$ , the  $*$ -homomorphisms  $\psi \oplus K \text{ev}_{x_0}, \gamma \oplus K \text{ev}_{x_0} : I_{p,q} \rightarrow M_{Kpq+1}(A)$  are homotopic for any point  $x_0 \in (0, 1)$ .*

*Proof.* Let  $a, b, m > 0$  be integers such that  $ap + bq = mpq + 1$ . Throughout the proof  $I_{p,q}$  will be denoted by  $B$ . Define  $*$ -homomorphisms  $\alpha, \beta : B \rightarrow M_{mpq+1}(B)$  by  $\alpha = \text{id}_B \oplus m(\text{ev}_{x_0} \otimes 1_B)$  and  $\beta = a(e_0 \otimes 1_B) \oplus b(e_1 \otimes 1_B)$ . Since  $B$  is semiprojective, there exist a finite subset  $\mathcal{F} \subset B$  and  $\delta > 0$  such that if  $\mu, \nu : B \rightarrow A$  are two unital  $*$ -homomorphisms such that  $\|\mu(f) - \nu(f)\| < \delta$  for all  $f \in \mathcal{F}$ , then  $\mu$  is homotopic to  $\nu$ . By Corollary 5.1 there are points  $t_1, \dots, t_r \in (0, 1)$  such that if  $\eta = (\text{ev}_{t_1} \otimes 1_B) \oplus (\text{ev}_{t_2} \otimes 1_B) \oplus \cdots \oplus (\text{ev}_{t_r} \otimes 1_B)$ , then there is a unitary  $u \in M_{(m+r)pq+1}(B)$  such that

$$\|u(\alpha(f) \oplus \eta(f))u^* - \beta(f) \oplus \eta(f)\| < \delta$$

for all  $f \in \mathcal{F}$ . By our choice of  $\mathcal{F}$  and  $\delta$ , it follows that  $u(\alpha \oplus \eta)u^*$  is homotopic to  $\beta \oplus \eta$ . Since the unitary group of  $M_{(m+r)pq+1}(B)$  is path connected [7] and since  $\eta$  is homotopic to  $r(\text{ev}_{x_0} \otimes 1_B)$  we deduce that  $\alpha \oplus r(\text{ev}_{x_0} \otimes 1_B)$  and  $\beta \oplus r(\text{ev}_{x_0} \otimes 1_B)$  are homotopic as  $*$ -homomorphisms from  $I_{p,q}$  to  $M_{(m+r)pq+1}(B)$ . Consequently, for any unital  $*$ -homomorphism  $\psi : B \rightarrow A$ ,

$$(\text{id}_{(m+r)pq+1} \otimes \psi) \circ (\alpha \oplus r(\text{ev}_{x_0} \otimes 1_B)) = \psi \oplus (m+r)(\text{ev}_{x_0} \otimes 1_A)$$

is homotopic to

$$(\text{id}_{(m+r)pq+1} \otimes \psi) \circ (\beta \oplus r(\text{ev}_{x_0} \otimes 1_B)) = a(e_0 \otimes 1_A) \oplus b(e_1 \otimes 1_A) \oplus r(\text{ev}_{x_0} \otimes 1_A).$$

It follows that if  $\gamma : B \rightarrow A$  is any other unital  $*$ -homomorphism, and  $K = m + r$ , then  $\psi \oplus K \text{ev}_{x_0}$  is homotopic to  $\gamma \oplus K \text{ev}_{x_0}$  since they are both homotopic to  $a(e_0 \otimes 1_A) \oplus b(e_1 \otimes 1_A) \oplus r(\text{ev}_{x_0} \otimes 1_A)$ .  $\square$

**Theorem 5.3.** *There is a constant  $L > 0$  such that the following statement holds: Let  $X$  be a compact metric space of covering dimension  $d < \infty$ , and let  $k \geq L(pq)^2(d+1)$  be a natural number. It follows that any two unital  $*$ -homomorphisms*

$$\phi, \psi : I_{p,q} \rightarrow C(X) \otimes M_k$$

*are homotopic.*

*Proof.* Set  $L = 16(K+1)$ , where  $K$  is the constant of Proposition 5.2. We will first prove the theorem under the assumption that  $X$  is a finite CW-complex, and requiring only that

$$k \geq \frac{L}{2}(pq)^2(d+1) = 8(K+1)(pq)^2(d+1).$$

We will then use the semiprojectivity of  $I_{p,q}$  to deduce the general case.

Assume that  $X$  is a finite CW-complex. Using Proposition 3.3 and the fact that  $\dim(X) = d$ , we may assume that  $N_g^\phi, N_g^\psi < d+1$ . Since  $\phi$  and  $\psi$  now satisfy the hypotheses of Corollary 4.6, we may simply assume that both  $\phi$  and  $\psi$  have a direct summand of the form

$$\bigoplus_{i=1}^M ev_{1/2},$$

where

$$M = \left\lfloor \frac{k - pq(8d+4)}{pq} \right\rfloor.$$

Straightforward calculation then shows that

$$k - Mpq \leq k - pq \left\lfloor \frac{k - pq(8d+4)}{pq} \right\rfloor \leq k - [k - pq(8d+5)] \leq 8pq(d+1).$$

Let us write

$$\phi = \phi' \oplus \left( \bigoplus_{i=1}^M ev_{1/2} \right); \quad \psi = \psi' \oplus \left( \bigoplus_{i=1}^M ev_{1/2} \right).$$

Set  $l = \text{rank}(\phi'(1)) = \text{rank}(\psi'(1)) \leq 8pq(d+1)$ , so that  $\phi', \psi' : I_{p,q} \rightarrow C(X) \otimes M_l$  are unital  $*$ -homomorphisms. Set

$$\phi'' = \phi' \oplus K(1_{C(X) \otimes M_l} \otimes ev_{1/2}); \quad \psi'' = \psi' \oplus K(1_{C(X) \otimes M_l} \otimes ev_{1/2}).$$

It follows from Proposition 5.2 that

$$\phi'', \psi'' : I_{p,q} \rightarrow C(X) \otimes M_{(Kpq+1)l}$$

are homotopic. Straightforward calculation shows that

$$Kl \leq 8Kpq(d+1) \leq \left\lfloor \frac{L(pq)^2(d+1) - pq(8d+4)}{pq} \right\rfloor \leq \left\lfloor \frac{k - pq(8d+4)}{pq} \right\rfloor = M.$$

We may therefore view  $\phi''$  and  $\psi''$  as direct summands of  $\phi$  and  $\psi$ , respectively:

$$\phi = \phi'' \oplus \left( \bigoplus_{i=1}^{M-Kl} ev_{1/2} \right); \quad \psi = \psi'' \oplus \left( \bigoplus_{i=1}^{M-Kl} ev_{1/2} \right).$$

The homotopy between  $\phi''$  and  $\psi''$  now provides the desired homotopy between  $\phi$  and  $\psi$ .

Now suppose that  $X$  is only a metric space of finite covering dimension  $d$ . We may embed  $X$  into a bounded subset of  $\mathbb{R}^{2d+1}$ , and so write  $X = \cap_n X_n$ , where  $(X_n)$  is a decreasing sequence of polyhedra. By the semiprojectivity of  $I_{p,q}$  we have

$$[I_{p,q}, M_k(C(X))] = \lim_{n \rightarrow \infty} [I_{p,q}, M_k(C(X_n))].$$

We may therefore assume that the homotopy classes of our given maps  $\phi$  and  $\psi$  lie in some  $[I_{p,q}, M_k(C(X_n))]$ . Having proved the theorem for finite CW-complexes, we conclude that  $\phi$  and  $\psi$  are homotopic if

$$k \geq \frac{L}{2}(pq)^2(\dim(X_n) + 1) \geq \frac{L}{2}(pq)^2(2d + 2) = L(pq)^2(d + 1).$$

This proves the theorem proper. □

**Corollary 5.4.** *Let  $p$  and  $q$  be relatively prime positive integers strictly greater than one, and let  $X$ ,  $L$ , and  $k$  be as in Theorem 5.3. Suppose that  $Y \subseteq X$  is closed, and that we are given a unital  $*$ -homomorphism  $\phi : I_{p,q} \rightarrow C(Y) \otimes M_k$ . It follows that there is a unital  $*$ -homomorphism  $\psi : I_{p,q} \rightarrow C(X) \otimes M_k$  such that  $\psi|_Y = \phi$ .*

*Proof.* By the semiprojectivity of  $I_{p,q}$  we can extend  $\phi$  to the closure of some open neighbourhood  $O$  of  $Y$ , i.e., we may assume that  $\phi : I_{p,q} \rightarrow C(\overline{O}) \otimes M_k$  without changing the original definition of  $\phi$  over  $Y$ . As explained in subsection 2.2,  $F^k$  is nonempty. Choose a point  $\gamma \in F^k$ . By Theorem 5.3,  $\phi$  and  $1_{C(\overline{O})} \otimes \gamma$  are homotopic as maps from  $I_{p,q}$  into  $C(\overline{O}) \otimes M_k$ . Let us denote this homotopy by

$$H : [0, 1] \rightarrow \text{Hom}_1(I_{p,q}; C(\overline{O}) \otimes M_k),$$

where  $H(0) = \phi$ .

Find a continuous map  $f : X \rightarrow [0, 1]$  which is equal to zero on  $Y$  and equal to one off  $O$ . Define  $\psi : I_{p,q} \rightarrow C(X) \otimes M_k$  by the formula

$$\psi_x = \begin{cases} H(f(x))_x, & x \in \overline{O} \\ \gamma, & x \notin \overline{O} \end{cases}$$

One checks that  $\psi$  so defined has the required property. □

6. MAPS FROM  $I_{p,q}$  INTO RECURSIVE SUBHOMOGENEOUS ALGEBRAS

**6.1. Recursive subhomogeneous algebras.** Let us recall some of the terminology and results from [12].

**Definition 6.1.** (i) if  $X$  is a compact Hausdorff space and  $k \in \mathbb{N}$ , then  $M_k(C(X))$  is a recursive subhomogeneous algebra (RSH algebra);  
(ii) if  $A$  is a recursive subhomogeneous algebra,  $X$  is a compact Hausdorff space,  $X^{(0)} \subseteq X$  is closed,  $\phi : A \rightarrow M_k(C(X^{(0)}))$  is a unital  $*$ -homomorphism, and  $\rho : M_k(C(X)) \rightarrow M_k(C(X^{(0)}))$  is the restriction homomorphism, then the pullback

$$A \oplus_{M_k(C(X^{(0)}))} M_k(C(X)) = \{(a, f) \in A \oplus M_k(C(X)) \mid \phi(a) = \rho(f)\}$$

is a recursive subhomogeneous algebra.

It is clear from the definition above that a  $C^*$ -algebra  $R$  is an RSH algebra if and only if it can be written in the form

$$(6) \quad R = \left[ \cdots \left[ \left[ C_0 \oplus_{C_1^{(0)}} C_1 \right] \oplus_{C_2^{(0)}} C_2 \right] \cdots \right] \oplus_{C_l^{(0)}} C_l,$$

with  $C_k = M_{n(k)}(C(X_k))$  for compact Hausdorff spaces  $X_k$  and integers  $n(k)$ , with  $C_k^{(0)} = M_{n(k)}(C(X_k^{(0)}))$  for compact subsets  $X_k^{(0)} \subseteq X$ , and where the maps  $C_k \rightarrow C_k^{(0)}$  are always the restriction maps. We call the  $C^*$ -algebra

$$R_k = \left[ \cdots \left[ \left[ C_0 \oplus_{C_1^{(0)}} C_1 \right] \oplus_{C_2^{(0)}} C_2 \right] \cdots \right] \oplus_{C_k^{(0)}} C_k$$

the  $k^{\text{th}}$  stage algebra of  $R$ . Let  $\text{Prim}_n(R)$  denote the space of irreducible representations of  $R$  of dimension  $n$ . We say that an RSH algebra has finite topological dimension if  $\dim(\text{Prim}_n(R))$  is finite for each  $n$ ; if  $R$  has finite topological dimension, then we call  $d := \max_n \dim(\text{Prim}_n(R))$  the *topological dimension* of  $R$ . If  $R$  is separable, then the  $X_k$  can be taken to be metrisable ([12, Proposition 2.13]). Finally, if  $R$  has no irreducible representations of dimension less than or equal to  $N$ , then we may assume that  $n(k) > N$ . We refer to the smallest of the  $n(k)$  as the *minimum matrix size* of  $R$ .

## 6.2. An existence theorem.

**Theorem 6.2.** Let  $R$  be a separable RSH algebra of finite topological dimension  $d$  and minimum matrix size  $n$ . Let  $p$  and  $q$  be relatively prime integers strictly greater than one. Suppose that  $n \geq L(pq)^2(d+1)$ , where  $L$  is the constant of Theorem 5.3. It follows that there is a unital  $*$ -homomorphism  $\gamma : I_{p,q} \rightarrow R$ .

*Proof.* We proceed by induction on the index  $k$  from subsection 6.1. We have a decomposition

$$R = \left[ \cdots \left[ \left[ C_0 \oplus_{C_1^{(0)}} C_1 \right] \oplus_{C_2^{(0)}} C_2 \right] \cdots \right] \oplus_{C_l^{(0)}} C_l$$

as in (6) above, where  $C_0 = M_{n(0)}(C(X_0))$  and  $n(0) \geq n > pq$ . As explained in subsection 2.2,  $F^{n(0)}$  is not empty. Choose  $\psi \in F^{n(0)}$ . It follows that  $\gamma_0 := 1_{C(X_0)} \otimes \psi$  defines a unital  $*$ -homomorphism from  $I_{p,q}$  into  $C_0$ .

Suppose  $k < l$ , and that we have found a unital  $*$ -homomorphism  $\gamma_k : I_{p,q} \rightarrow R_k$ . We will prove that  $\gamma_k$  can be extended to a unital  $*$ -homomorphism  $\gamma_{k+1} : I_{p,q} \rightarrow R_{k+1}$ . Starting with  $\gamma_0$  and applying this inductive result repeatedly will yield the map  $\gamma$  required by the theorem. We have

$$R_{k+1} = R_k \oplus_{C_{k+1}^{(0)}} C_{k+1}.$$

Notice that  $\gamma_k$  defines a unital  $*$ -homomorphism from  $I_{p,q}$  into  $R_k \oplus C_{k+1}^{(0)}$  in a natural way—the map into the summand  $R_k$  is simply  $\gamma_k$  itself, while the map into the summand  $C_{k+1}^{(0)}$  is the composition of  $\gamma_k$  with the clutching map  $\phi : R_k \rightarrow C_{k+1}^{(0)}$  (cf. Definition 6.1). Viewing  $R_{k+1}$  as a subalgebra of  $R_k \oplus C_{k+1}$ , we see that our task is simply to extend the map  $\phi \circ \gamma_k : I_{p,q} \rightarrow C_{k+1}^{(0)}$  to all of  $C_{k+1} = M_{n(k+1)}(C(X_{k+1}^{(0)}))$ . Since  $n(k+1) \geq n \geq L(pq)^2(d+1)$ , the existence of the desired extension follows from Corollary 5.4.  $\square$

### 6.3. Proof of Theorem 1.1.

*Proof.* Let  $A$  be a unital separable  $C^*$ -algebra. By [16, Proposition 6.3], it will suffice to prove that for any  $I_{p,q}$ , there is a unital  $*$ -homomorphism  $\gamma : I_{p,q} \rightarrow A^{\otimes \infty}$ .

By hypothesis, there is a unital subalgebra  $S$  of  $A^{\otimes \infty}$  which is separable, subhomogeneous, and has no characters. By the main result of [10],  $S$  is the limit of an inductive system  $(R_i, \phi_i)$ , where each  $R_i$  is a (unital) separable RSH algebra of finite topological dimension and each  $\phi_i$  is injective and unital. Suppose, contrary to our desire, that  $X_i := \text{Prim}_1(R_i) \neq \emptyset$  for each  $i \in \mathbb{N}$ . Each  $\phi_i : R_i \rightarrow R_{i+1}$  induces a continuous map  $\phi_i^\# : X_{i+1} \rightarrow X_i$ . Since each  $X_i$  is compact, the limit of the inverse system  $(X_i, \phi_{i-1}^\#)$  is not empty. In other words, there is an element of  $X_1$  which has a pre-image in  $X_{i+1}$  under each composed map  $\phi_1^\# \circ \dots \circ \phi_i^\#$ . It follows that  $S$  has a character, contrary to our assumption. We therefore conclude that  $R_i$  has no characters for some  $i \in \mathbb{N}$ . Since the  $\phi_i$  are injective, we have that  $A^{\otimes \infty}$  contains, unittally, a recursive subhomogeneous algebra  $R := \phi_{i\infty}(R_i)$  of finite topological dimension which has no characters.

Let  $n > 1$  be the minimum matrix size of  $R$ . Find a natural number  $m$  such that  $n^m/(md+1) > L(pq)^2$ . It follows from [12, Proposition 3.4] that the topological dimension of  $R^{\otimes m}$  is at most  $md$ , while the minimum matrix size of  $R^{\otimes m}$  is at least  $n^m$ . Applying Theorem 6.2 we obtain a unital  $*$ -homomorphism

$$\gamma : I_{p,q} \rightarrow R^{\otimes m} \hookrightarrow (A^{\otimes \infty})^m \cong A^{\otimes \infty},$$

as required.  $\square$

**6.4. Examples.** Let us explain now why the examples (a)-(f) of the introduction satisfy the hypotheses of Theorem 1.1

- (a) Let  $A$  be a unital simple separable exact  $C^*$ -algebra containing an infinite projection. It follows from a result of Kirchberg ([8]) that  $A^{\otimes \infty}$ —even  $A^{\otimes 2}$ —is purely infinite and simple, and so has real rank zero. By Proposition 5.7 of [11], there is a unital  $*$ -homomorphism  $\phi : F \rightarrow A^{\otimes \infty}$ , where  $F$  is a finite-dimensional (hence subhomogeneous)  $C^*$ -algebra without characters.
- (b) Let  $A$  be a unital separable ASH algebra without characters. Following the arguments in the proof of Theorem 1.1, we see that there must be a unital subalgebra of  $A$  which is subhomogeneous without characters.
- (c) If  $A$  is properly infinite, then there is a unital embedding of  $\mathcal{O}_\infty$  into  $A$ ;  $\mathcal{O}_\infty$  is  $\mathcal{Z}$ -stable by the Kirchberg-Phillips classification, and so any  $I_{p,q}$  embeds unitaly into  $A$ .
- (d) Let  $A$  be a unital separable  $C^*$ -algebra of real rank zero. By Proposition 5.7 of [11], there is a unital map  $\phi : F \rightarrow A$ , where  $F$  is a finite-dimensional  $C^*$ -algebra without characters.
- (e) Let  $X$  be a compact infinite metric space, and  $\alpha : X \rightarrow X$  a minimal homeomorphism. It follows from Theorem 2.7 of [9] that the crossed product  $C^*(X, \mathbb{Z}, \alpha)$  contains a recursive subhomogeneous algebra without characters.
- (f) There are several examples which show that Banach algebra  $K$ -theory and traces do not form a complete invariant for simple unital separable amenable  $C^*$ -algebras. The first of these is due to Rørdam, and consists of a simple unital separable amenable  $C^*$ -algebra  $A$  containing both a finite and an infinite projection. By the theorem of Kirchberg cited in (a) we have that  $A \otimes A$  is purely infinite, and so following the arguments of (a) we see that  $A$  satisfies the hypotheses of Theorem 1.1. Other examples were produced by the second name author in [17] and [18]. These algebras are ASH and non-type-I, and so satisfy the hypotheses of Theorem 1.1 by the arguments of (b) above.

## 7. CONCLUDING REMARKS

One consequence of Theorem 6.2 is the following:

**Corollary 7.1.** *Let  $A$  be a simple separable unital non-type-I inductive limit of RSH algebras with slow dimension growth. Given any relatively prime integers  $p, q > 1$ , there is a unital  $*$ -homomorphism  $\phi : I_{p,q} \rightarrow A$ .*

This result may be viewed as a step toward proving that an algebra  $A$  as in Corollary 7.1 is  $\mathcal{Z}$ -stable. To get the stronger conclusion one needs to parlay the map  $\phi$  into an approximately central sequence of  $*$ -homomorphisms  $\phi_n : I_{p,q} \rightarrow A$ . This improvement, however difficult it may be to realise technically, is at least eminently reasonable for reasons of spectral multiplicity. Given an inductive sequence  $(A_i, \gamma_i)$  of RSH algebras with slow dimension growth (see [12] for the definition of this property), one knows that the commutant of the

image of  $A_i$  in  $A_j$  over each point in the spectrum of  $A_j$  is well-approximated by a finite-dimensional  $C^*$ -algebra  $F$ , all of whose simple summands have large dimension compared with the dimension of the spectrum of  $A_j$ . It stands to reason that one should be able to map an RSH algebra, all of whose matrix fibres are large in comparison with its topological dimension, into the approximate commutant of the image of a finite set  $F \subseteq A_i$  in  $A_j$ . An application of Theorem 6.2 will then provide a  $*$ -homomorphism  $\phi : I_{p,q} \rightarrow A_j$  which almost commutes with the image of  $F$  in  $A_j$ , leading to the  $\mathcal{Z}$ -stability of  $A = \lim_{i \rightarrow \infty} (A_i, \gamma_i)$ .

Proving that  $A$  as in Corollary 7.1 is  $\mathcal{Z}$ -stable would be an extremely important step toward the confirmation of Elliott's classification conjecture for simple unital separable ASH algebras of slow dimension growth, and would, given Winter's recent classification theorem ([20]) and the decomposition results of Lin and Phillips ([9]), already confirm Elliott's conjecture for the class of all crossed product  $C^*$ -algebras arising from the action of a minimal uniquely ergodic diffeomorphism with smooth inverse on a compact manifold.
